Abstract: - TV white spaces (TVWS) can be utilized by Secondary Users (SUs) equipped with cognitive radio functionality on the condition that they do not cause harmful interference to Primary Users (PUs). Optimization of power allocation is necessary when there is a high density of secondary users in a network in order to reduce the level of interference among SUs and to protect PUs against harmful interference. Grey Wolf Optimizer (GWO) is relatively recent population based metaheuristic algorithm that has shown superior performance compared to other population based metaheuristic algorithms. Recent trend has been to hybridize population based metaheuristic algorithms in order to avoid the problem of getting trapped in a local optimum. This paper presents the design and analysis of performance of a hybrid grey wolf optimizer and Firefly Algorithm (FA) with Particle Swarm Optimization problem. Matlab was used for simulation. The hybrid of GWO, FA and PSO (HFAGWOPSO) reduces sum power by 81.42% compared to GWO and improves sum throughput by 16.41% when compared to GWO. Simulation results also show that the algorithm has better convergence rate.

Key-Words: - TV White Spaces, power allocation, cognitive radio, grey wolf optimizer, firefly algorithm, particle swarm optimization.

1 Introduction

Spectrum occupancy assessments conducted in Spain, USA, New Zealand, Singapore and Germany [1] and UK [2] indicate that a significant percentage of spectrum allocated to Primary Users (PUs) is not being fully utilized. Spectrum is considered a scarce resource. The number of devices that need access to spectrum continue to increase and yet the available useful spectrum is limited. Dynamic Spectrum Access (DSA) is currently being seen as one of the remedies to spectrum scarcity and spectrum underutilization [3], [4], [5]. This is because DSA provides an efficient way for spectrum sharing and spectrum management. DSA allows the use of any frequency channel not being used by PUs or any other bands that are not being used such as guard TV white space (TVWS) band has bands[6]. attracted interest among the DSA industrial and research community because of its good propagation characteristics. TVWS is the frequency band that is

not being used by TV transmitters in the UHF band [7].

In order to improve Quality of Service (QoS) in a TVWS network and to ensure protection of PUs against any harmful interference, there is need to optimize power allocation. Power allocation in a TVWS network is an NP hard optimization problem. Among other heuristic algorithms. population based metaheuristic algorithms are preferred for NP hard optimization problems [8]. This because such algorithms have better ability for global exploration and local exploitation in searching the solution space in addition to having reasonable time complexity [9]. Despite the advantages of population based metaheuristic algorithms, they can get trapped in a local optimum [10] and this results in premature convergence. Recent trend has been to hybridize evolutionary algorithms so as to overcome the shortcoming by improving either the exploration or exploitation ability or both [10], [11].

Grey wolf optimizer is a relatively recent population based metaheuristic algorithm that has shown very good performance [12], [13]. Just like other population based metaheuristic algorithms, it can also suffer premature convergence. The objective of this paper is to present the design and analysis of performance of a hybrid of grey wolf optimizer and firefly algorithm with particle swarm optimization (HFAGWOPSO) operators for power allocation in a TVWS network as a continuous optimization problem. This paper seeks to find out whether hybridizing GWO with FA and PSO will improve the performance of GWO. HFAGWOPSO is further compared with a few other population based metaheuristic algorithms. Simulation results show that compared to grey wolf optimizer (GWO), firefly algorithm (FA), PSO, genetic algorithm (GA) and hybrid FA, GA and PSO (FAGAPSO) [14], HFAGWOPSO achieves the highest sum throughput, lowest sum power and the best convergence rate.

The rest of the paper is organized as follows. Section 2 provides a review of related work. Section 3 provides an overview of relevant is algorithms. Section 4 presents the design of HFAGWOPSO. System model and simulation set up are presented in section 5 and 6, respectively. Performance evaluation of HFAGWOPSO is discussed in section 7. The paper is concluded in section 8.

2 Related Work

This section presents a review of related work on power allocation in a TVWS network using population based metaheuristic algorithms. In [15], we proposed a firefly algorithm based power allocation algorithm for a TVWS network which makes use of a Geo-location Database (GLDB) and that considers interference constraints at both PU and SUs. In this paper, the performance of HFAGWOPSO is compared to that of both FA and GWO.

We compared the performance of various hybrid FA with GA and PSO algorithms for power allocation in a TVWS network in [14]. Results in the paper showed the performance of FA improves when it is hybridized with PSO and GA. In this paper the performance of HFAGWOPSO is compared to that of hybrid FA, GA and PSO (FAGAPSO) as well as pure FA, PSO and GA.

Our previous work in [5] presents the use of modified FA for joint power and spectrum allocation for a TVWS network. FA is modified to solve a continuous-discrete optimization problem. In this paper, only power allocation is considered.

3 Overview of Relevant Algorithms

This section provides a brief overview of GWO, FA, GA and PSO algorithms.

3.1 Grey Wolf Optimizer

GWO is a population based metaheuristic algorithm that is derived from the social behavior of grey wolves that prefer to live in a pack made up of 5-12 wolves [12], [16]. Grey wolves have a strict social hierarchy. The wolves at the top of the hierarchy are called alphas. The second, third and fourth in the hierarchy are beta, delta and omega, respectively. The alpha makes decisions such as hunting, where to sleep and wake up time. The rest of the wolves have to follow the decision made by the alpha. The beta wolf assists the alpha in the decision making and is the one to take over in case the alpha dies or ages. The beta follows the decision of the alpha but gives instructions to lower ranked wolves. Sentinels, scouts, elders and caretakers all fall into the category of delta wolves. The omegas are the lowest in the ranking and are the last to eat. Omega wolves take instructions from all wolves. A wolf that is not an alpha, beta or omega is called a delta. They follow instructions from alpha and beta but dominate the omega.

Group hunting is another social behavior of grey wolves. Grey wolves will first of all track, chase and approach the prey. After that they will, pursue, encircle and harass the prey until it stops moving. The final phase of the hunting is for the wolves to make an attack towards the prey.

The GWO algorithm models the two social behaviors of wolves of social hierarchy and group hunting. Each wolf in the pack represents a potential solution to the optimization problem. The fittest solution is called the alpha (α). The second and third best solutions are called beta (β) and delta (δ), respectively. The rest of the candidate solutions are assumed to be omega (ω). The hunting is led by α , β and δ . ω follow these three candidates. Equation (1) is used mathematically model the encircling behaviour of wolves.

$$\vec{X}(t+1) = \vec{X}_p(t) + \vec{A}.\vec{D},$$
 (1)

where *D* is as defined in equation (2), *t* is the iteration number, \vec{A} and \vec{C} are coefficient vectors as defined in equations (3) and (4), $\vec{X_p}$ is the position of prey, and \vec{X} is the position of grey wolf.

$$\vec{D} = |\vec{C}.\vec{X}_p(t) - \vec{X}(t),$$
 (2)

$$\vec{A} = 2a.\,\vec{r_1} - a,\tag{3}$$

$$\vec{C} = 2\vec{r_2}, \qquad (4)$$

where *a* is decreased linearly from 2 to 0 over the course of iterations, r_1 and r_2 are random vectors in [0,1]. In order to replicate the hunting behaviour of grey wolves, the alpha, beta and delta are assumed to have better knowledge about the potential position of prey. All the other wolves will then have to update their positions of their search agents according to position of the best search agents (alpha, beta and delta). The position of wolves are updated according to equation (5).

$$\vec{X}(t+1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3}$$
 (5)

where \vec{X}_1, \vec{X}_2 and \vec{X}_3 are defined in equations (6), (7) and (8).

$$\vec{X}_1 = \vec{X}_{\alpha} - \vec{A}_1 \cdot (\vec{D}_{\alpha}),$$
 (6)

$$\vec{X}_2 = \vec{X}_\beta - \vec{A}_2. (\vec{D}_\beta),$$
 (7)

$$\vec{X}_3 = \vec{X}_\delta - \vec{A}_3. (\vec{D}_\delta).$$
 (8)

where \vec{X}_{α} , \vec{X}_{β} and \vec{X}_{δ} are the positions of the first best three solutions, \vec{A}_1 , \vec{A}_2 and \vec{A}_3 are defined in equations (6), (7) and (8) and \vec{D}_{α} , \vec{D}_{β} , and \vec{D}_{δ} are defined in equations (9), (10) and (11).

$$\vec{D}_{\alpha} = |\vec{C}_1 \cdot \vec{X}_{\alpha} - \vec{X}|, \qquad (9)$$

$$\vec{D}_{\beta} = |\vec{C}_2 \cdot \vec{X}_{\beta} - \vec{X}|, \qquad (10)$$

$$\vec{D}_{\delta} = |\vec{C}_3.\vec{X}_{\delta} - \vec{X}|, \qquad (11)$$

where \vec{C}_1, \vec{C}_2 and \vec{C}_3 are defined in equation (4). Parameter *a*, that contols the balance between exploration and exploitation, is updated according to (12).

$$a = 2 - t \frac{2}{MaxIter}, \qquad (12)$$

where t is the iteration number and *MaxIter* is the maximum number of iterations. Algorithm 1 represents the pseudocode for GWO algorithm.

Algorithm 1: Grey Wolf Optimizer [12] Initialize the grey wolf population X_i (i=1,2,...,n) with random power values that are within allowed range Initialize *a*, *A* and *C* • • Compute the fitness of each wolf • Set \vec{X}_{α} as the best wolf Set \vec{X}_{β} as the second best wolf. Set \vec{X}_{δ} as the third best wolf. while (t < *MaxIter*) for each wolf Update the current wolf position using equation (5)end for Update a, A and C. Compute the fitness of all search agents Update \vec{X}_{α} , \vec{X}_{β} and \vec{X}_{δ} . t = t + 1end while • return \vec{X}_{α}

3.2 Firefly Algorithm

FA mimics the behavior of fireflies. Firefly is an insect that flash to either attract a mate or potential prey [17]. Flashing may also serve as a warning mechanism. The flashing of a firefly is rhythmic. For female fireflies, the attractiveness of male fireflies depends on its brightness. The light intensity has an inverse relationship with distance. Light intensity reduces as distance increases according to this formula: $I \alpha \frac{1}{r^2}$. Fireflies, therefore, are visible within a limited distance. The objective function of an optimization problem can be associated with the flashing. The light intensity is determined by brightness I which is associated with an objective function value. In an optimization problem, each firefly represents a potential solution the optimization problem. Variation of to attractiveness with distance is given by:

$$\beta = \beta_0 e^{-\gamma r^2},\tag{13}$$

where the term β denotes to firefly light intensity, r is the distance between two fireflies and γ is the light absorption co-efficient. For any two flashing fireflies, a firefly with less brightness will move towards a brighter one as per to equation (14).

$$x_i^{t+1} = x_i^t + \beta_o e^{-\gamma r_{ij}^2} \left(x_j^t - x_i^t \right) + \alpha_t \epsilon_t^i, \quad (14)$$

where the terms x_i and x_j are the locations of fireflies *i* and *j*, α is a randomization parameter and the term ϵ_t^i is a vector of random numbers. The first term stands for attractiveness while the second term stands for randomization. The symbol *t* is the

iteration number. The distance between fireflies, r_{ij} , is computed according to equation (15):

$$r_{ij} = \sqrt{(x_{i,t} - x_{j,t})^2}$$
 (15)

Algorithm 2: Firefly Algorithm[18]

Initialize the control parameter values for the FA: light absorption coefficient γ , attractiveness β , randomization parameter α , maximum number of iterations t_{max} , number of fireflies NP, domain space D. Step 2 Define objective function $f \rightarrow x, x = x_1, x_2, x_3, \dots, x_n$. Generate the initial location of fireflies x_i ($i = 1, 2, \dots, NP$) and set the iteration number $t = 0$. 3.3 Particle Swarm Optimization Algorithm

PSO is inspired by a flock of birds flying towards a destination. Each candidate solution is referred to as a particle. Each particle represents a bird in the flock. Unlike GA, no new birds/particles are generated. The existing particles are improved iteratively. The birds adjust their social behavior as they move towards the destination. Birds communicate as they fly. As they communicate they identify the bird which is in the best position and then they move towards it at a certain velocity. PSO combines both local search and global search. Local search is represented by each bird learning from their own experience. Global search is represented by each bird learning from the experience of others. PSO starts by generating a set of particles with a random solutions in the to the optimization problem. The fitness of each particle is then evaluated. Each particle looks at three parameters: its current position X_i , its current best position P_i and associated objective function value P_{best} , and its flying velocity V_i . At every iteration X_i and associated objective function value P_{best} is updated if there is an improvement in P_i . The best particle, P_{best} , is also determined at every iteration. The global best particle P_g and associated objective function value g_{best} is also updated if the current P_{best} is better than g_{best} at every iteration. At every iteration also, each particle flies towards P_i and P_g at a certain velocity. Each particle updates its current velocity, V_i , according to the equation (16):

New
$$V_i = \omega \times current V_i + c_1 \times rand() \times (P_i - X_i) + c_2 \times rand() \times (P_a - X_i)$$
, (16)

where c_1 and c_2 are two positive constants and rand() is a random function. The term ω plays the role of balancing local search and global search. With the new current velocity, the position of the particle is then updated according to the equation (17):

New position
$$X_i$$
 = current position X_i +
New V_i , (17)

$$V_{min} \ge V_i \ge -V_{max}, \quad (18)$$

where V_{max} is the maximum particle velocity and V_{min} is the minimum particle velocity.

PSO has been applied for power allocation in a CRN in [19]. In the proposed algorithm, the objective is to maximize signal to interference noise ratio (SINR) for all SUs. Each particle (X_i) , represents a potential solution to the problem of finding optimal power and spectrum allocation to all SUs. Initially SUs are assigned power randomly. The objective function used is minimization of minimum SINR violation. At each iteration the best power vector for each particle (P_i) and global best power vector (P_q) are updated if there is an improvement. At every iteration, X_i will then moves towards (P_i) and (P_g) at a certain velocity. After a fixed number of iterations, P_g will be selected as the optimal solution to the problem of power assignment.

3.4 Hybrid Firefly and Particle Swarm **Optimization Algorithms**

Arunachalam et. al. [20] proposed a hybrid FA and PSO for problem of combined economic and emission dispatch including valve point effect. In the proposed algorithm, there is no modification to firefly algorithm but the initial solution is obtained from PSO. The authors argue that quality of the final solution of FA depends on the initial solution. Simulation results show that hybrid the algorithm performs better than both PSO and FA.

Kora P. and Krishna K. [21] also proposed a hybrid FA and PSO algorithm for detection of bundle branch block. The hybrid algorithm makes use of PSO concepts and parameters. The concepts of personal best and global best which are absent in FA are introduced. All the steps in FA remain the same with that of the proposed algorithm except that equation (2.2) of the FA that represents firefly movement is changed to incorporate the idea of personal best and global best. In the proposed algorithm, each firefly movement involves a move towards the local personal best (P_i) and global best (P_g) .

$$x_{i}^{t+1} = x_{i}^{t} + c_{1}e^{-\gamma r_{ij}^{2}}(p_{i} - x_{i}^{t}) + c_{2}e^{-\gamma r_{ij}^{2}}(p_{g} - x_{i}^{t}) + \alpha_{t}\epsilon_{t}^{i}.$$
(19)

4 Hybridizing Grey wolf optimizer with Firefly Algorithm and Particle **Swarm Optimization**

Grey wolf optimizer searches the solution space according to the position of alpha, beta and delta that are assumed to know the position of prey. In GWO, the term a in equation (3) is decreased linearly from 2 to 0 over the course of iterations. At the start, \vec{A} (equation 3) has values greater than 1 or less than -1 so that there is exploration through divergence from prey position (approximated by alpha, beta and delta). As a reduces over the course of iterations, divergence from alpha, beta and delta reduces and hence exploration of the solution space becomes limited. Although the values of r_1 and r_2 remain as random vectors in [0,1] throughout the course of iterations, their values do not significantly influence exploration.

Grey wolf optimizer is hybridized FA with PSO operators in this paper so as to enhance exploration. This is illustrated in Algorithm 3. Firefly movement using PSO operators is added to the original GWO algorithm in step 2.5. Firefly movement will add an extra exploration or divergence term to GWO in order prevent premature convergence. Firefly movement using PSO operators is made use of because it was found to enhance the performance of firefly algorithm in [14].

Algorithm 3: Hybrid Grev Wolf Optimizer and **Firefly Algorithm with PSO Operators Step 1: Initialization**

- **1.1** Initialize the grey wolf population X_i (i=1,2,...,n) with random power values that are within allowed range
- **1.2** Initialize *a*, *A* and *C* • 1.3 Compute the fitness of each wolf
- **1.4** Set \vec{X}_{α} as the best wolf •
- **1.5** Set \vec{X}_{β} as the second best wolf. •
- **1.6** Set \vec{X}_{δ} as the third best wolf. •

Step 2

5 System Model

The optimization problem to be considered is about power allocation optimization described in our previous paper in [15]. Network shown in Figure 1 is considered. One TV receiver put near the border of the protection zone. Of all the TV receivers in the protection zone, a TV receiver at that location is much more vulnerable to interference because it receives the lower transmit power from TV tower compared to other TV receivers. A TV receiver at that location also receives the highest interference from SUs because it is nearest to the secondary cell. Protection ratio at the TV receiver should not fall below the required protection ratio threshold. The network consists of M channels and N SUs.

The optimization problem is defined as follows [15]:

Problem 1

 $p^* = \arg\min\phi(p) \tag{20}$

subject to $C: p_{min} \leq p_i \leq p_{max}$.

where

The optimization problem in Problem 1 is about minimization of sum power and interference threshold violations at SUs and at the PU. In equation (20), the first term, $\varphi(p)$, represents the sum power of all SUs, the second term $(c_s \sum_{i=1}^{N} \max[0, g_i^s]^2)$ represents interference threshold violation for SUs while the third term represents interference threshold violation for PU. The terms g_i^s and g_i^p refer to SINR threshold for SU and PU, respectively. c_s and c_p are penalty factors for SU interference threshold violation and PU interference threshold violation, respectively.

TVWS power allocation optimization Problem 1 is then solved using Algorithm 4. Each wolf in a prey hunting pack in GWO algorithm represents a potential solution to power allocation in a TVWS network.

Figure 1: Interference scenario

6 Simulation Set Up

Simulation parameters are laid out in Table I. Matlab R2016a was used for simulation. Matlab is selected because it has diverse mathematical functions. SUs (N = 1000) are randomly distributed across an area of 1 km². Fig. 2 illustrates the network diagram created in Matlab. The channels to be considered are the ones in Nairobi central business district shown in Fig.3.

Algorithm 4: TVWS Power Allocation Using HFAGWOPSO

Step 1

- Specify the number of SUs
- Set the dimension of each wolf, *D*, as the number of SUs

• Initialize *a*, *A* and *C* **Step 2**

- Initialize the grey wolf pack with random power values for each SU,*d*, and for each wolf as asearch agent $x_i = [x_{1,i}, x_{2,i}, \dots, x_{d,i}, \dots, x_{D,i}]$
- Check wolf x_i to see if the power vector values of each search agent (wolf) are within allowed range. If any values are not within range then create values that are within range in a random manner to replace them.
- Calculate the fitness of each search agent using Equation (13)
- Determine \vec{X}_{α} , \vec{X}_{β} and \vec{X}_{δ}

Step 3

- while (t<*MaxIter*)
 - o for each search agent
 - Update the position of the current search agent using equation (5)

end for

- $\circ \quad \text{Update a, A and C.}$
- Calculate the fitness of all search agents using Equation (21)
- $\circ \quad \mbox{Check wolf } x_i \mbox{ and find out if the power vector values of each search agent (wolf) are within range. If any of the values are out of range then generate values in a random manner that are within range to replace them. }$
- Update \vec{X}_{α} , \vec{X}_{β} and \vec{X}_{δ} .
- For every firefly (wolf), move it towards a better solution (as per equation 21) according to equation (19).
 t = t + 1 end while

Step 4 • return \vec{X}_{α}

SUs are distributed in a random manner all through the 10 channels (M =10). The free space path loss model was used to model path loss [22]:

$$PL(d) = 20 \log(d) + 20 \log(f) - 147.55,$$
 (22)

where d is the distance from sending antenna to receiving antenna in meters and f is the frequency of the device. Algorithm 2 is then used to assign power to SUs.

Parameter	Value	Description	
b_m	6 MHz	TV channel bandwidth	
f_a	650 MHz	DTV signal centre frequency	
P _{TV}	-70.6 dBm	Received DTV signal power at TV receiver	
δ_n^2	-102dBm	Noise power	
ωο	23 dB	SINR threshold of TV receiver	
$ ho_o$	7 dB	SINR threshold of SU	
P ^{BS}	36 dBm (4W)	Base station transmit power	
p_{max}	30 dBm	Maximum transmit power of SU	
G_{SU}	10 dB	Antenna gain of SU	
G_{PU}	10 dB	Antenna gain of PU	
G_{BS}	10 dB	Antenna gain of access point	

Table I: Simulation Parameters

• SU

Figure 2: Network Diagram

Figure 3: Network diagram

FA parameters used: number of fireflies NP = 50, $\beta_o = 1$, $\alpha = 30$, $\gamma = 10$. Parameters used for GWO: *a* starts with 2. PSO parameters used: inertia weights: $w_{max} = 4$ and $w_{min} = 2$, number of particles = 50, social parameter $c_1 = 2$ and cognitive parameter $c_2 = 2$. GA parameters used : number of chromosomes=50, selection rate = 0.5 and mutation rate = 0.8. Parameters used for FA are as follows: $\beta_o = 1$, $\alpha = 30$, $\gamma = 10$. The number of iterations used is 500. Other parameters used are outlined in Table I.

7 Performance Evaluation

In this section, performance of HFAGWOPSO for power allocation in a TVWS network is compared with grey wolf optimizer (GWO), particle swarm optimization (PSO), genetic algorithm (GA) and firefly algorithm (FA). The performance metrics used are sum power, sum throughput, percentage of SUs less than threshold, objective function value and running time.

7.1 Sum Power

Table II shows comparison of the HFAGWOPSO with the rest of the algorithms in terms of sum power in the network. The results show that the HFAGWOPSO achieves the lowest sum power. HFAGWOPSO reduces sum power by 81.42%, 99.91%, 99.90%, 99.91% and 99.16% compared to GWO, GA, PSO, FA and FAGAPSO, respectively. This is because of the better power allocation achieved by the algorithm.

Algorithm	Sum Power (Watts)	Percentage Reduction
HFAGWOPSO	1.68	
GWO	9.04	81.42%
GA	1824	99.91%
PSO	1751	99.90%
FA	1789	99.91%
FAGAPSO	199	99.16%

Table II: Comparison of Sum Power

7.2 Sum Throughput

Table III shows performance comparison of the HFAGWOPSO with the rest of the algorithms in terms of sum throughput in the network. HFAGWOPSO improves sum throughput by 16.41%, 151.70%, 150.06%, 153.17% and 60.20% when compared to GWO, GA, PSO, FA and FAGAPSO, respectively. This is because of the improved power allocation that minimizes interference in the network. According to Shannon channel capacity theorem, reduction in interference improves throughput.

Algorithm	Sum Throughput (Gbps)	Percentage Increase
HFAGWOPSO	65.04	
GWO	55.87	16.41%
GA	25.84	151.70%
PSO	26.01	150.06%
FA	25.69	153.17%
FAGAPSO	40.6	60.20%

Table III: Comparison of Sum Throughput

7.3 Percentage of SUs less than SU SINR Threshold

Table IV shows performance comparison of HFAGWOPSO with the rest of the algorithms in terms of percentage of SUs with SU SINR less than required threshold of 7dB in the network. The results show that the GWO achieves the lowest percentage of SUs with SU SINR below threshold. This is because of the improved power allocation that minimizes interference in the network.

Table IV: Comparison of Percentage of SUs Less Than SU SINR Threshold

Algorithm	Percentage of SUs
	less than SU SINR
	Threshold
HFAGWOPSO	0.76%
GWO	1.5%
GA	15.84%
PSO	15.66%
FA	16.54%
FAGAPSO	5.04%

7.4 Objective Function Value

Table V shows comparison HFAGWOPSO with the rest of the algorithms in terms of achieved objective function value. The results show that HFAGWOPSO achieves the best (lowest) objective function value represented by equation (20).

Table V: Comparison of Objective Function

values			
Algorithm	Objective	Percentage	
	Function	Reduction	
	Value		
HFAGWOPSO	2438		
GWO	2510	2.87%	
GA	20600	88.17%	
PSO	17318	85.92%	
FA	20312	88.00%	
FAGAPSO	4415	81.09%	

7.5 Rate of Convergence

Convergence curve for the algorithms under consideration for 300 iterations are shown in Figures 4 and 5. Figure 4 shows a comparison of all the algorithms. Figure 5 shows a zoomed in comparison of convergence curves for HFAGWOPSO, GWO and FAGAPSO.

Figure 4: Comparison of Convergence Curve

Figure 5: Zoomed in Comparison of Convergence Curve for FAGAPSO, GWO and HFAGWOPSO

The figures show that HFAGWOPSO has the best convergence rate followed by GWO. This is because of firefly movement with PSO operators that is introduced into GWO that improves its exploration ability. HFAGWOPSO has a better objective function value compared to GWO at every iteration. It can be seen that the addition of firefly movement with PSO operators into GWO improves the convergence of GWO.

7.6 Analysis of Performance of HFAGWOPSO

Power allocation in a TVWS network is a continuous optimization problem. Results have shown that for a continuous optimization problem, HFAGWOPSO is superior to all the algorithms under consideration. Results have shown that HFAGWOPSO outperforms GWO, GA, FA, PSO and FAGAPSO in terms of objective function value, sum power and sum throughput. HFAGWOPSO also has the best convergence rate.

Performance of population based metaheuristic algorithm depends on exploration ability and exploitation ability [10], [11], [23]. There needs to be a sustained exploration in addition exploitation over the course of iterations of the algorithm. Convergence curve in Figures 4 and 5 shows GWO has a better ability to balance between exploration and exploitation and hence it is able to continuously improve objective function value for the entire 300 iterations unlike FA, GA and PSO. FA, GA and PSO converge to a solution which cannot improve after fifteen iterations because they have a poor exploration ability compared to HFAGWOPSO and GWO.

8 Conclusion

In this paper, a TVWS network power allocation algorithm based on hybrid grey wolf optimizer and firefly algorithm has been presented. Simulation results show that HFAGWOPSO achieves the best sum throughput, sum power and percentage of SUs less than SU SINR threshold. HFAGWOPSO also has the best convergence rate. Addition of firefly movement into GWO will increase the running time of GWO. Future work analyzing the running time and complexity of the algorithm and find areas of improvement.
