**Abstract:** The thermal convection of a plasma in porous medium is investigated to include simultaneously the effect of rotation and the finiteness of the ion Larmor radius (FLR) in the presence of a vertical magnetic field. Following linear stability theory and normal mode analysis method, the dispersion relation is obtained. It is found that the presence of a uniform rotation, finite Larmor radius and magnetic field introduces oscillatory modes in the system which were, otherwise, non-existent in their absence. When the instability sets in as stationary convection, finite Larmor radius, rotation, medium permeability and magnetic field are found to have stabilizing (or destabilizing) effects under certain conditions. In the absence of rotation, finite Larmor radius has stabilizing effect on the thermal instability of the system whereas the medium permeability and the magnetic field may have stabilizing or destabilizing effect under certain conditions. The conditions

$$\kappa < \left[ \varepsilon + (1 - \varepsilon) \frac{\rho_S C_S}{\rho_0 C} \right] \eta \quad \text{and} \quad \kappa < \frac{\varepsilon^2 \left[ \varepsilon + (1 - \varepsilon) \frac{\rho_S C_S}{\rho_0 C} \right] \nu}{P^2 \left[ \varepsilon P \{ \sqrt{U}(x - 2) + \sqrt{T_{A_1}} \}^2 - 2Q_1 \right]}$$

are the sufficient conditions for non-existence of overstability, the violation of which does not necessary involve an occurrence of overstability.

**Key-Words:** Thermal convection; plasma; finite Larmor radius effect; rotation; porous medium

## 1 Introduction

The theoretical and experimental results on thermal convection in a fluid layer, under varying assumptions of hydrodynamics and hydromagnetics, have been discussed in a treatise by Chandrasekhar [1]. The effects of the finiteness of the ion Larmor radius which exhibits itself in the form of ‘magnetic viscosity’ in the fluid equations have been studied by many authors (Jukes [2]; Vandakurov [3]). Sharma and Prakash [4] have studied the effect of finite Larmor radius on the thermal instability of a plasma. Melchior and Popowich [5] have considered the finite Larmor radius effect on the Kelvin-Helmholtz instability in a fully ionized plasma while that on Rayleigh-Taylor instability has been studied by Singh and Hans [6]. The effect

of finite Larmor radius on the thermal instability of a plasma in the presence of a vertical magnetic field has been studied by Sharma [7]. Bhatia and Chhonkar [8] investigated the simultaneous effects of rotation and finite Larmor radius on the Rayleigh-Taylor instability of two viscous fluids.

The study of the breakdown of the stability of a layer of fluid subject to a vertical temperature gradient in porous medium and the possibility of convective flow is of considerable interest in recent years. The study of onset of convection in a porous medium has attracted considerable interest because of its natural occurrence and of its intrinsic importance in many industrial problems, particularly in petroleum-exploration, chemical and nuclear industries. The derivation of the basic equations of a layer of fluid heated from below in porous medium,

using Boussinesq approximation, has been given by Joseph [9]. The study of a layer of fluid heated from below in porous media is motivated both theoretically and by its practical applications in engineering disciplines. Among the applications in engineering disciplines one can find the food process industry, chemical process industry, solidification and centrifugal casting of metals. The development of geothermal power resources has increased general interest in the properties of convection in porous medium. Lapwood [10] has studied the stability of convective flow in a porous medium using Rayleigh's procedure. The Rayleigh instability of a thermal boundary layer in flow through a porous medium has been considered by Wooding [11].

The properties of ionized space and laboratory magnetic fluids (plasmas) have been intensively investigated theoretically and experimentally in the past sixty years. One of the key aspects studied in this context is the stability of plasma structures. Usually, instabilities can be divided into two categories: macro- and micro-instabilities. Macro-instabilities occur with low frequencies compared to the plasma and cyclotron frequency and they are studied within the framework of magnetohydrodynamics (MHD). Physicists have understood the behaviour of macro-instabilities and they showed how to avoid the most destructive of them, but small-scale gradient driven micro-instabilities are still a serious obstacle for having a stable plasma for a large range of parameters. Micro-instabilities are described by models which include, e.g. finite Larmor radius (FLR) and collisionless dissipative effects in plasmas. Time and length scales of micro-instabilities are comparable to the turbulent length scales and the length scales of transport coefficients. In general, the FLR effect is neglected. However, when the Larmor radius becomes comparable to the hydromagnetic length of the problem (e.g. wavelength) or the gyration frequency of ions in the magnetic field is of the same order as the wave frequency, finiteness of the Larmor radius must be taken into account. Strictly speaking, the space and time scale for the breakdown of hydromagnetics are on the respective scales of ion gyration about the field, and the ion Larmor frequency. In the present paper, we

explore the effect of FLR on the thermal instability of a plasma in porous medium. Finite Larmor radius effect on plasma instabilities has been the subject of many investigations. In many astrophysical plasma situations such as in solar corona, interstellar and interplanetary plasmas the assumption of zero Larmor radius is not valid. Roberts and Taylor [12] and Rosenbluth et al. [13] have shown the stabilizing influence of finite ion Larmor radius (FLR) effects on plasma instabilities. Hernegger [14] investigated the stabilizing effect of FLR on thermal instability and showed that thermal criterion is changed by FLR for wave propagation perpendicular to the magnetic field. Sharma [15] investigated the stabilizing effect of FLR on thermal instability of rotating plasma. Ariel [16] discussed the stabilizing effect of FLR on thermal instability of conducting plasma layer of finite thickness surrounded by a non-conducting matter. Vaghela and Chhajlani [17] studied the stabilizing effect of FLR on magneto-thermal stability of resistive plasma through a porous medium with thermal conduction. Bhatia and Chhonkar [18] investigated the stabilizing effect of FLR on the instability of a rotating layer of self-gravitating plasma incorporating the effects of viscosity and Hall current. Vyas and Chhajlani [19] pointed out the stabilizing effect of FLR on the thermal instability of magnetized rotating plasma incorporating the effects of viscosity, finite electrical conductivity, porosity and thermal conductivity. Kaothekar and Chhajlani [20] investigated the problem of Jeans instability of self-gravitating rotating radiative plasma with finite Larmor radius corrections. Thus FLR effect is an important factor in the discussion of thermal convection and other hydromagnetic instabilities. Keeping these in mind, an attempt is made to study the effects of finite Larmor radius and rotation on the thermal convection of incompressible plasma in porous medium in the present paper.

## 2 Formulation of the Problem and Perturbation Equations

Consider an infinite, horizontal, incompressible, viscous and electrically conducting plasma layer of depth  $d$  bounded by the planes  $z = 0$  and  $z = d$  in an isotropic and homogeneous medium of porosity  $\varepsilon$  and medium permeability  $k_1$ . This layer is heated from below such that a steady temperature gradient  $\beta (= |dT/dz|)$  is maintained. Temperatures and densities at the bottom surface  $z = 0$  are  $T_0$  and  $\rho_0$  and at the upper surface  $z = d$  are  $T_1$  and  $\rho_1$  respectively. The system is acted on by a uniform vertical magnetic field  $\vec{H}(0, 0, H)$ , a uniform rotation  $\vec{\Omega}(0, 0, \Omega)$  and gravity field  $\vec{g}(0, 0, -g)$ . Let  $\rho, T, \alpha, \kappa, g, \mu_e, \mu, \nu (= \frac{\mu}{\rho_0}), \eta$  and  $\vec{P}$  denote, respectively, the density, temperature, coefficient of thermal expansion, thermal diffusivity, gravitational acceleration, magnetic permeability, viscosity, kinematic viscosity, electrical resistivity and stress tensor taking into account the finite Larmor radius effect. When the plasma flows through a porous medium, the gross effect is represented by Darcy's law. As a result, the resistance term  $-\left(\frac{\mu}{k_1}\right) \vec{q}$  replaces the usual viscous term, here  $\vec{q}$  stands for the filter velocity of the plasma. Then the equations expressing the conservation of momentum, mass and heat are

$$\frac{1}{\varepsilon} \left[ \frac{\partial \vec{q}}{\partial t} + \frac{1}{\varepsilon} (\vec{q} \cdot \nabla) \vec{q} \right] = -\frac{1}{\rho_0} \nabla \left( \vec{P} - \frac{1}{2\varepsilon^2} |\vec{\Omega} \times \vec{q}|^2 \right) + \vec{g} \left( 1 + \frac{\delta \rho}{\rho_0} \right) + \frac{\mu_e}{4\pi\rho_0} (\nabla \times \vec{H}) \times \vec{H} - \frac{\nu}{k_1} \vec{q} + \frac{2}{\varepsilon} (\vec{q} \times \vec{\Omega}), \quad (1)$$

$$\nabla \cdot \vec{q} = 0, \quad (2)$$

$$\frac{\partial T}{\partial t} + (\vec{q} \cdot \nabla) T = \kappa \nabla^2 T, \quad (3)$$

where  $\kappa = \varepsilon + (1 - \varepsilon) \frac{\rho_s C_s}{\rho_0 C}$ ;  $\rho_0, C$  are the density and heat capacity of the plasma and  $\rho_s, C_s$  are the density and the heat capacity of the solid (porous) material respectively.

The equation of the state is

$\rho = \rho_0 [1 - \alpha(T - T_0)]$ , where the suffix zero refers to the values at the reference level  $z = 0$ .

The Maxwell's equations yield

$$\varepsilon \frac{d\vec{H}}{dt} = (\vec{H} \cdot \nabla) \vec{q} + \varepsilon \eta \nabla^2 \vec{H}, \quad (4)$$

$$\nabla \cdot \vec{H} = 0, \quad (5)$$

where  $d/dt = \partial/\partial t + (1/\varepsilon)(\vec{q} \cdot \nabla)$  stands for the convective derivative.

For the magnetic field along the  $z$ -axis, the stress tensor  $\vec{P}$ , taking into account the finite ion gyration radius (Vandakurov [3]), has the components

$$\begin{aligned} P_{xx} &= p - \rho_0 \nu_0 \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right), \\ P_{xy} &= P_{yx} = \rho_0 \nu_0 \left( \frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right), \\ P_{xz} &= P_{zx} = -2\rho_0 \nu_0 \left( \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right), \\ P_{yy} &= p + \rho_0 \nu_0 \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right), \\ P_{yz} &= P_{zy} = 2\rho_0 \nu_0 \left( \frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \right), \\ P_{zz} &= p, \end{aligned} \quad (6)$$

where  $p$  is the scalar part of the pressure and  $\rho_0 \nu_0 = Nk^*T/4\omega_H$ ,  $\omega_H$  being the ion-gyration frequency,  $k^*$  is Boltzman constant, while  $N$  and  $T$  are number density and temperature of the ions, respectively.

The steady state solution is

$$\vec{q} = (0, 0, 0), T = T_0 - \beta z, \rho = \rho_0(1 + \alpha\beta z), \quad (7)$$

where  $\beta = \frac{T_0 - T_1}{d}$  is the magnitude of uniform temperature gradient which is maintained and is positive as temperature decreases upwards.

Now we consider a small perturbation on the steady state and let  $\delta\rho, \delta\vec{P}, \theta, \vec{q}(u, v, w)$  and  $\vec{h}(h_x, h_y, h_z)$  denote, respectively, the perturbations in density, stress tensor,

temperature, hydromagnetic fluid velocity (initially zero) and the magnetic field. The change in density  $\delta\rho$ , caused by the perturbation  $\theta$  in temperature, is given by

$$\delta\rho = -\alpha\rho_0\theta. \quad (8)$$

Then the linearized hydromagnetic perturbation equations relevant to the problem are

$$\begin{aligned} \frac{1}{\varepsilon} \frac{\partial \vec{q}}{\partial t} = & -\frac{1}{\rho_0} \nabla \delta \vec{P} + \vec{g} \left( \frac{\delta \rho}{\rho_0} \right) + \frac{\mu_e}{4\pi\rho_0} (\nabla \times \vec{h}) \\ & \times \vec{H} - \frac{v}{k_1} \vec{q} \\ & + \frac{2}{\varepsilon} (\vec{q} \times \vec{\Omega}), \end{aligned} \quad (9)$$

$$\nabla \cdot \vec{q} = 0, \quad (10)$$

$$E \frac{\partial \theta}{\partial t} = \beta w + \kappa \nabla^2 \theta, \quad (11)$$

$$\varepsilon \frac{\partial \vec{h}}{\partial t} = (\vec{H} \cdot \nabla) \vec{q} + \varepsilon \eta \nabla^2 \vec{h}, \quad (12)$$

$$\nabla \cdot \vec{h} = 0. \quad (13)$$

Within the framework of the Boussinesq approximation, equations (9) – (13) become

$$\begin{aligned} \left( \frac{\partial}{\partial t} + \frac{v\varepsilon}{k_1} \right) \nabla^2 = & \varepsilon g \alpha \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \theta \\ & + \frac{\mu_e H \varepsilon}{4\pi\rho_0} \frac{\partial}{\partial z} (\nabla^2 h_z) \\ & + \varepsilon v_0 \left( \nabla^2 - 3 \frac{\partial^2}{\partial z^2} \right) \frac{\partial \zeta}{\partial z} \\ & - 2\Omega \frac{\partial \zeta}{\partial z}, \end{aligned} \quad (14)$$

$$\begin{aligned} \left( \frac{\partial}{\partial t} + \frac{v\varepsilon}{k_1} \right) \zeta = & \frac{\mu_e \varepsilon H}{4\pi\rho_0} \frac{\partial \xi}{\partial z} - \varepsilon v_0 \left( \nabla^2 - 3 \frac{\partial^2}{\partial z^2} \right) \frac{\partial w}{\partial z} \\ & + 2\Omega \frac{\partial w}{\partial z}, \end{aligned} \quad (15)$$

$$\varepsilon \frac{\partial \xi}{\partial t} = H \frac{\partial \zeta}{\partial z} + \varepsilon \eta \nabla^2 \xi \quad (16)$$

$$\left[ E \frac{\partial}{\partial t} - \kappa \nabla^2 \right] \theta = \beta w, \quad (17)$$

$$\varepsilon \left[ \frac{\partial}{\partial t} - \eta \nabla^2 \right] h_z = H \frac{\partial w}{\partial z}, \quad (18)$$

where  $\nabla^2 = \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$

and  $\zeta = \partial v/\partial x - \partial u/\partial y$ ;  $\xi = \partial h_y/\partial x - \partial h_x/\partial y$

stand for the z-components of vorticity and current density, respectively.

### 3 Dispersion Relation

Analyzing the disturbances into normal modes, we assume that the perturbation quantities are of the form

$$\begin{aligned} [w, h_z, \zeta, \xi, \theta] \\ = [W(z), K(z), Z(z), X(z), \Theta(z)] \exp[ik_x x \\ + ik_y y + nt], \end{aligned} \quad (19)$$

where  $k_x$  and  $k_y$  are the wave numbers along the  $x$  – and  $y$  – directions, respectively,  $k = \sqrt{k_x^2 + k_y^2}$  is the resultant wave number, and  $n$  is, in general, a complex constant.

Using expression (19), equations (14)-(18) in non-dimensional form transform to

$$\begin{aligned} \left( \frac{\sigma}{\varepsilon} + \frac{1}{P_l} \right) (D^2 - a^2) W + \left( \frac{gd^2}{v} \right) a^2 \alpha \Theta \\ - \frac{\mu_e Hd}{4\pi\rho_0 v} (D^2 - a^2) DK \\ + \left( \frac{v_0 d}{v} \right) (2D^2 + a^2) DZ + \frac{2\Omega d^3}{v\varepsilon} DZ \\ = 0, \end{aligned} \quad (20)$$

$$\begin{aligned} \left( \frac{\sigma}{\varepsilon} + \frac{1}{P_l} \right) Z \\ = \left( \frac{\mu_e Hd}{4\pi\rho_0 v} \right) DX + \left( \frac{v_0}{vd} \right) (2D^2 + a^2) DW \\ + \frac{2\Omega d}{v\varepsilon} DW, \end{aligned} \quad (21)$$

$$\begin{aligned} [D^2 - a^2 - Ep_1\sigma] \Theta \\ = - \left( \frac{\beta d^2}{\kappa} \right) W, \end{aligned} \quad (22)$$

$$[D^2 - a^2 - p_2\sigma] K = - \left( \frac{Hd}{\varepsilon\eta} \right) DW, \quad (23)$$

$$[D^2 - a^2 - p_2\sigma]X = -\left(\frac{Hd}{\varepsilon\eta}\right)DZ, \quad (24)$$

where we have introduced new coordinates  $(x^*, y^*, z^*) = (x/d, y/d, z/d)$  in the new unit of length  $d$  and  $D = d/dz^*$ . For convenience, the asterisks are dropped hereafter. Also we have put  $a = kd$  and  $\sigma = nd^2/\nu$ ,  $p_1 = \nu/\kappa$  is the Prandtl number,  $p_2 = \nu/\eta$  is the magnetic Prandtl number and  $P_l = k_1/d^2$  is the dimensionless medium permeability.

Here we consider the case where both boundaries are free as well as perfect conductors of heat, while the adjoining medium is electrically non-conducting. The case of two free boundaries is slightly artificial, except in stellar atmospheres (Spiegel [21]) and in certain geophysical situations where it is most appropriate. However, the case of two free boundaries allows us to obtain analytical solution without affecting the essential features of the problem. The appropriate boundary conditions, with respect to which equations (20) – (24) must be solved, are

$$W = D^2W = 0, DZ = 0, \Theta = 0, X = 0 \text{ at } z = 0 \text{ and } 1, \quad (25)$$

on a perfectly conducting boundary.

The tangential components of the magnetic field are continuous in the absence of any surface current. Another boundary condition is

$$DK = 0 \text{ on the boundaries,} \quad (26)$$

in addition to other boundary conditions given by the equation (25).

Using the above boundary conditions, it can be shown that all the even order derivatives of  $W$  must vanish for  $z = 0$  and  $1$  and hence the proper solution of  $W$  characterizing the lowest mode is

$$W = W_0 \sin \pi z, \quad (27)$$

where  $W_0$  is a constant.

Eliminating  $Z, K, X$  and  $\Theta$  between equations (20) - (24) and substituting the proper solution

(27) in the resultant equation, we obtain the dispersion relation

$$\begin{aligned} &R_1 x \\ &= (1+x) \left( \frac{i\sigma_1}{\varepsilon} + \frac{1}{P} \right) (1+x + iE p_1 \sigma_1) \\ &+ Q_1 \frac{(1+x)(1+x + iE p_1 \sigma_1)}{\varepsilon(1+x + i p_2 \sigma_1)(1+x + iE p_1 \sigma_1)} \\ &+ \frac{[\sqrt{U}(x-2) + \sqrt{T_{A_1}}]^2}{\left[ (1+x + i p_2 \sigma_1) \left( \frac{i\sigma_1}{\varepsilon} + \frac{1}{P} \right) + \frac{Q_1}{\varepsilon} \right]}, \end{aligned} \quad (28)$$

where

$$Q = \frac{\mu_e H^2 d^2}{4\pi\rho_0\nu\eta}, R = \frac{g\alpha\beta d^4}{\nu\kappa}, U = \frac{\nu_0^2}{\nu^2},$$

stand for the Chandrasekhar number, the thermal Rayleigh number, a non-dimensional number accounting for the finite Larmor radius, respectively, and we have also put

$$\begin{aligned} x &= \frac{a^2}{\pi^2}, P = \pi^2 P_l, i\sigma_1 = \frac{\sigma}{\pi^2}, Q_1 = \frac{Q}{\pi^2}, R_1 \\ &= \frac{R}{\pi^4}, T_{A_1} = \frac{4\Omega^2 d^4}{\nu^2} \text{ (Taylor number)}, T_{A_1} \\ &= \frac{T_A}{\varepsilon^2 \pi^4} \text{ and } i = \sqrt{-1}. \end{aligned}$$

## 4 Important Theorems and Discussion

**Theorem 1:** The system is stable or unstable.

**Proof:** Multiplying equation (20) by  $W^*$ , the complex conjugate of  $W$ , and using equations (21) - (24) together with the boundary conditions (25) and (26), we obtain

$$\begin{aligned} &\left(\frac{\sigma}{\varepsilon} + \frac{1}{P_l}\right) I_1 - \frac{g\alpha\kappa a^2}{\nu\beta} (I_2 + E p_1 \sigma^* I_3) \\ &+ \frac{\mu_e \eta \varepsilon}{4\pi\rho_0\nu} (I_4 + p_2 \sigma^* I_5) \\ &+ d^2 \left(\frac{\sigma^*}{\varepsilon} + \frac{1}{P_l}\right) I_6 \\ &+ \frac{\mu_e \eta d^2 \varepsilon}{4\pi\rho_0\nu} (I_7 + p_2 \sigma I_8) \\ &= 0, \end{aligned} \quad (29)$$

where

$$\begin{aligned}
 I_1 &= \int_0^1 (|DW|^2 + a^2|W|^2) dz, \\
 I_2 &= \int_0^1 (|D\Theta|^2 + a^2|\Theta|^2) dz, \\
 I_3 &= \int_0^1 (|\Theta|^2) dz, \\
 I_4 &= \int_0^1 (|D^2K|^2 + 2a^2|DK|^2 + a^4|K|^2) dz, \\
 I_5 &= \int_0^1 (|DK|^2 + a^2|K|^2) dz, \\
 I_6 &= \int_0^1 (|Z|^2) dz, \\
 I_7 &= \int_0^1 (|DX|^2 + a^2|X|^2) dz, \\
 I_8 &= \int_0^1 (|X|^2) dz, \tag{30}
 \end{aligned}$$

and  $\sigma^*$  is the complex conjugate of  $\sigma$ . The integrals  $I_1, \dots, \dots, I_8$  are all positive definite. Putting  $\sigma = \sigma_r + i\sigma_i$  and equating the real and imaginary parts of equation (29), we obtain

$$\begin{aligned}
 &\left[ \frac{I_1}{\varepsilon} + \frac{\mu_e \eta \varepsilon p_2}{4\pi \rho_0 \nu} (I_5 + d^2 I_8) - \frac{g \alpha \kappa a^2}{\nu \beta} E p_1 I_3 \right. \\
 &\quad \left. + \frac{d^2}{\varepsilon} I_6 \right] \sigma_r = \\
 &- \left[ \frac{1}{P_l} I_1 + \frac{\mu_e \eta \varepsilon}{4\pi \rho_0 \nu} (I_4 + d^2 I_7) - \frac{g \alpha \kappa a^2}{\nu \beta} I_2 \right. \\
 &\quad \left. + \frac{d^2}{P_l} I_6 \right], \tag{31}
 \end{aligned}$$

and

$$\begin{aligned}
 &\left[ \frac{I_1}{\varepsilon} + \frac{g \alpha \kappa a^2}{\nu \beta} E p_1 I_3 - \frac{\mu_e \eta \varepsilon p_2}{4\pi \rho_0 \nu} (I_5 - d^2 I_8) \right. \\
 &\quad \left. - \frac{d^2}{\varepsilon} I_6 \right] \sigma_i \\
 &= 0. \tag{32}
 \end{aligned}$$

It is evident from equation (31) that  $\sigma_r$  may be positive or negative i.e. there may be instability or stability in the presence of rotation, finite Larmor radius and magnetic field in porous medium which is also true in their absence.

**Theorem 2:** The modes may be oscillatory or non-oscillatory in contrast to case of no magnetic field, and in the absence of rotation, finite Larmor radius and magnetic field where modes are non-oscillatory.

**Proof:** Equation (32) yields that  $\sigma_i$  may be zero or non-zero, which means that the modes may be non-oscillatory or oscillatory. In the absence of rotation, finite Larmor radius and magnetic field, equation (32) reduces to

$$\sigma_i \left[ \frac{I_1}{\varepsilon} + \frac{g \alpha \kappa a^2}{\nu \beta} E p_1 I_3 \right] = 0 \tag{33}$$

and the terms in brackets are positive definite. Thus  $\sigma_i = 0$ , which means that oscillatory modes are not allowed and the principle of exchange of stabilities is satisfied for a porous medium in the absence of rotation, finite Larmor radius and magnetic field. The oscillatory modes are introduced due to the presence of rotation, magnetic field and finite Larmor radius which were non-existent in their absence.

**Theorem 3:** The system is stable for  $\frac{g \alpha \kappa}{\nu \beta} \leq \frac{27\pi^4}{4}$  and under the condition  $\frac{g \alpha \kappa}{\nu \beta} > \frac{27\pi^4}{4}$ , the system becomes unstable.

**Proof:** From equation (32), it is clear that  $\sigma_i$  is zero when the quantity multiplying it is not zero and arbitrary when this quantity is zero.

If  $\sigma_i \neq 0$ , then equation (31) gives

$$\begin{aligned}
 &\frac{I_1}{\varepsilon} + \frac{\mu_e \eta d^2 \varepsilon}{4\pi \rho_0 \nu} p_2 I_8 \\
 &= \frac{\mu_e \eta \varepsilon}{4\pi \rho_0 \nu} p_2 I_5 + \frac{d^2}{\varepsilon} I_6 \\
 &\quad - \frac{g \alpha \kappa a^2}{\nu \beta} E p_1 I_3
 \end{aligned}$$

Substituting this in equation (30), we get

$$\begin{aligned}
 &\frac{2\sigma_r I_1}{\varepsilon} + \frac{1}{P_l} I_1 + \frac{\mu_e \eta \varepsilon}{4\pi \rho_0 \nu} I_4 + d^2 \left( \frac{1}{P_l} \right) I_6 \\
 &\quad + \frac{\mu_e \eta d^2 \varepsilon}{4\pi \rho_0 \nu} I_7 \\
 &\quad + \frac{2\sigma_r \mu_e \eta d^2 \varepsilon}{4\pi \rho_0 \nu} p_2 I_8 \\
 &= \frac{g \alpha \kappa a^2}{\nu \beta} I_2. \tag{34}
 \end{aligned}$$

Equation (34) on using Rayleigh-Ritz inequality gives

$$\begin{aligned} & \frac{(\pi^2 + a^2)^3}{a^2} \int_0^1 |W|^2 dz \\ & + \frac{(\pi^2 + a^2)}{a^2} \left\{ \frac{2\sigma_r \mu_e \eta d^2 \varepsilon}{4\pi\rho_0\nu} p_2 I_8 + \frac{\mu_e \eta d^2 \varepsilon}{4\pi\rho_0\nu} I_7 \right. \\ & \left. + d^2 \left( \frac{1}{P_l} \right) I_6 + \frac{\mu_e \eta \varepsilon}{4\pi\rho_0\nu} I_4 + \frac{1}{P_i} I_1 + \frac{2\sigma_r}{\varepsilon} I_1 \right\} \\ & \leq \frac{g\alpha\kappa}{\beta\nu} \int_0^1 |W|^2 dz . \end{aligned} \quad (35)$$

Therefore, it follows from equation (35) that

$$\begin{aligned} & \left[ \frac{27\pi^4}{4} - \frac{g\alpha\kappa}{\nu\beta} \right] \int_0^1 |W|^2 dz \\ & + \frac{(\pi^2 + a^2)}{a^2} \left\{ \frac{2\sigma_r \mu_e \eta d^2 \varepsilon}{4\pi\rho_0\nu} p_2 I_8 \right. \\ & + \frac{\mu_e \eta d^2 \varepsilon}{4\pi\rho_0\nu} I_7 + d^2 \left( \frac{1}{P_l} \right) I_6 \\ & \left. + \frac{\mu_e \eta \varepsilon}{4\pi\rho_0\nu} I_4 + \frac{1}{P_i} I_1 + \frac{2\sigma_r}{\varepsilon} I_1 \right\} \\ & \leq 0 \end{aligned} \quad (36)$$

since minimum value of  $\frac{(\pi^2+a^2)^3}{a^2}$  with respect to  $a^2$  is  $\frac{27\pi^4}{4}$ .

Now, let  $\sigma_r \geq 0$ , we necessary have from (36) that

$$\frac{g\alpha\kappa}{\nu\beta} > \frac{27\pi^4}{4} . \quad (37)$$

Hence, if

$$\frac{g\alpha\kappa}{\nu\beta} \leq \frac{27\pi^4}{4} , \quad (38)$$

then  $\sigma_r < 0$ . Therefore, the system is stable. Thus, under condition (38), the system is stable and under condition (37) the system becomes unstable.

**Theorem 4:** For stationary convection case:

- (I) If  $x > 2$ , both finite Larmor radius and rotation have a stabilizing effect on the system. On the other hand if  $x < 2$ , finite Larmor radius has stabilizing (or destabilizing) effect and rotation

has destabilizing (or stabilizing) effect if

$$(x - 2) > (or <) \left( \frac{T_{A_1}}{U} \right)^{1/2} .$$

- (II) In the presence of finite Larmor radius effect and rotation if

$$\left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]^2 > (or <) \left\{ \sqrt{U}(x-2) + \sqrt{T_{A_1}} \right\}^2 (1+x)$$

the medium permeability has a destabilizing (or stabilizing) and the magnetic field has a stabilizing (or destabilizing) effect on the system.

- (III) In the absence of rotation, finite Larmor radius always has a stabilizing effect on the system whereas the medium permeability and the magnetic field may have stabilizing effect for some wave numbers and destabilizing effect for other wave numbers given by

$$U(x-2)^2(1+x) \geq \left( \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right)^2 .$$

**Proof:** When the instability sets in as stationary convection, the marginal state will be characterized by  $\sigma = 0$ . Putting  $\sigma = 0$ , the dispersion relation (28) reduces to

$$\begin{aligned} R_1 & = \left( \frac{1+x}{x} \right) \left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right] \\ & + \frac{\left[ U^{1/2}(x-2) + T_{A_1}^{1/2} \right]^2 (1+x)^2}{x \left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]} , \end{aligned} \quad (39)$$

which expresses the modified Rayleigh number  $R_1$  as a function of the dimensionless wave number  $x$  and the parameters  $Q_1, U P$  and  $T_{A_1}$ . To study the effects of finite Larmor radius, rotation, medium permeability and magnetic field on  $R_1$ , we examine the nature of  $dR_1/dU, dR_1/dT_{A_1}, dR_1/dP$  and  $dR_1/dQ_1$  analytically.

- (I) It follows from equation (39),

$$\frac{dR_1}{dU} = \frac{(x-2)(1+x)^2 \left[ (x-2) + \left(\frac{T_{A1}}{U}\right)^{1/2} \right]}{x \left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]}, \quad (40)$$

and

$$\frac{dR_1}{dT_{A1}} = \frac{(1+x)^2 \left(\frac{U}{T_{A1}}\right)^{1/2} \left[ (x-2) + \left(\frac{T_{A1}}{U}\right)^{1/2} \right]}{x \left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]}. \quad (41)$$

If  $x > 2$ , both finite Larmor radius and rotation have a stabilizing effect on the system.

If  $x < 2$ , finite Larmor radius has stabilizing (or destabilizing) effect and rotation has destabilizing (or stabilizing) effect if

$$(x-2) > (\text{or } <) \left(\frac{T_{A1}}{U}\right)^{1/2}. \quad (42)$$

(II) Also equation (39) yields

$$\frac{dR_1}{dP} = -\frac{(1+x)}{xP^2} \left[ \frac{\left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2 - \left\{ \sqrt{U}(x-2) + \sqrt{T_{A1}} \right\}^2}{\left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2} \right], \quad (43)$$

and

$$\frac{dR_1}{dQ_1} = \left(\frac{1+x}{\varepsilon x}\right) \left[ \frac{\left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2 - \left\{ \frac{\sqrt{U}(x-2) + \sqrt{T_{A1}}}{\sqrt{T_{A1}}} \right\}^2 (1+x)}{\left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2} \right], \quad (44)$$

In the equations (43) and (44) if

$$\left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]^2 > \left\{ \sqrt{U}(x-2) + \sqrt{T_{A1}} \right\}^2 (1+x), \quad (45)$$

then

$$\frac{dR_1}{dP} < 0 \text{ and } \frac{dR_1}{dQ_1} > 0,$$

which exhibits the destabilizing effect of medium permeability and stabilizing effect of magnetic field respectively.

Again if

$$\left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]^2 < \left\{ \sqrt{U}(x-2) + \sqrt{T_{A1}} \right\}^2 (1+x), \quad (46)$$

then

$$\frac{dR_1}{dP} > 0 \text{ and } \frac{dR_1}{dQ_1} < 0,$$

which shows the stabilizing effect of medium permeability and destabilizing effect of the magnetic field on the thermal instability of a plasma in porous media in the light of condition (46).

(III) In the absence of rotation,

$$\frac{dR_1}{dU} = \frac{(x-2)^2(1+x)^2}{x \left[ \frac{1+x}{P} + \frac{Q_1}{\varepsilon} \right]} > 0, \quad (47)$$

$$\frac{dR_1}{dP} = -\frac{(1+x)^2 \left[ -U(x-2)^2(1+x) \right]}{xP^2 \left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2}, \quad (48)$$

and

$$\frac{dR_1}{dQ_1} = \left(\frac{1+x}{\varepsilon x}\right) \left[ \frac{\left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2 - \left[ -U(x-2)^2(1+x) \right]}{\left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2} \right]. \quad (49)$$

Now

$$\frac{dR_1}{dP} \geq 0 \text{ and } \frac{dR_1}{dQ_1} \leq 0$$

according as

$$U(x-2)^2(1+x) \geq \left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2. \quad (50)$$

Thus in the absence of rotation, finite Larmor radius always has a stabilizing effect on the thermal instability of plasma whereas the

medium permeability and magnetic field may have stabilizing effect for some wave numbers and destabilizing effect for other wave numbers given by relation (50).

**Theorem 5:** The sufficient conditions for the non-existence of overstability are

$$\kappa < \left[ \varepsilon + (1 - \varepsilon) \frac{\rho_S C_S}{\rho_0 C} \right] \eta \text{ and}$$

$$\kappa < \frac{\varepsilon^2 \left[ \varepsilon + (1 - \varepsilon) \frac{\rho_S C_S}{\rho_0 C} \right] \nu}{P^2 \left[ \varepsilon P \left\{ \sqrt{U}(x - 2) + \sqrt{T_{A_1}} \right\}^2 - 2Q_1 \right]}$$

**Proof:** Here we discuss the possibility of whether instability may occur as overstability. Since for overstability, our interest is to determine the critical Rayleigh number for the onset of instability via a state of pure oscillations, it will suffice to find conditions for which equation (28) will admit solutions with  $\sigma_1$  real.

Assuming  $\sigma_1$  to be real and equating the real and imaginary parts of equation (28) and eliminating  $R_1$  between them, we obtain

$$A_3 C_1^3 + A_2 C_1^2 + A_1 C_1 + A_0 = 0, \quad (51)$$

where  $C_1 = \sigma_1^2$ ,  $b = 1 + x$  and

$$A_3 = \frac{b p_2^4}{\varepsilon^2} \left( \frac{E p_1}{P} + \frac{b}{\varepsilon} \right), \quad (52)$$

$$A_0 = \frac{b^6}{\varepsilon p^2} + \left[ \left( \frac{E p_1}{p^3} + \frac{2Q_1}{\varepsilon^2 p} \right) - \left\{ \frac{\sqrt{U}(b-3) - \sqrt{T_{A_1}}}{\varepsilon} \right\}^2 \right] b^5 + \left[ \frac{Q_1^2}{\varepsilon^3} + \frac{Q_1}{\varepsilon p^2} (3E p_1 - p_2) + \left\{ \sqrt{U}(b-3) + \sqrt{T_{A_1}} \right\}^2 \frac{E p_1}{P} \right] b^4 + \left[ \frac{Q_1^2}{\varepsilon^2 p} (3E p_1 - 2p_2) + \left\{ \sqrt{U}(b-3) + \sqrt{T_{A_1}} \right\}^2 \left( \frac{p_2 Q_1}{\varepsilon} + \frac{E p_1 Q_1}{\varepsilon} \right) \right] b^3 + \frac{Q_1^3}{\varepsilon^3} (E p_1 - p_2) b^2. \quad (53)$$

The values of coefficients  $A_1$  and  $A_2$  are not written here because their expressions are very lengthy and also not needed in the discussion of overstability. Since  $\sigma_1$  is real for overstability, the three values of  $C_1 (= \sigma_1^2)$  are positive. The product of the roots of (51) is  $-A_0/A_3$  and if this is to be positive, then  $A_0$  must be negative since from (52)  $A_3$  is positive.

It is clear from (53) that  $A_0$  is always positive if

$$E p_1 > p_2, \quad \text{and} \quad \left( \frac{E p_1}{p^3} + \frac{2Q_1}{\varepsilon^2 p} \right) > \frac{1}{\varepsilon} \left\{ \sqrt{U}(b-3) + \sqrt{T_{A_1}} \right\}^2 \quad (54)$$

which implies that

$$\kappa < \left[ \varepsilon + (1 - \varepsilon) \frac{\rho_S C_S}{\rho_0 C} \right] \eta \text{ and } \kappa < \frac{\varepsilon^2 \left[ \varepsilon + (1 - \varepsilon) \frac{\rho_S C_S}{\rho_0 C} \right] \nu}{P^2 \left[ \varepsilon P \left\{ \sqrt{U}(x - 2) + \sqrt{T_{A_1}} \right\}^2 - 2Q_1 \right]} \quad (55)$$

The inequalities (55) are, therefore, the sufficient conditions for the non-existence of overstability, the violation of which does not necessarily imply the occurrence of overstability.

## 5 Conclusions

The thermal convection of a plasma in porous medium in the presence of finite Larmor radius effect, rotation and vertical magnetic field is considered in the present paper. The main conclusions from the analysis of this paper are as follows:

- It is found that rotation, finite Larmor radius and uniform magnetic field introduce oscillatory modes in the system which were non-existent in their absence.
- It is observed that the system is stable for  $\frac{g\alpha\kappa}{\nu\beta} \leq \frac{27\pi^4}{4}$  and under the condition  $\frac{g\alpha\kappa}{\nu\beta} > \frac{27\pi^4}{4}$ , the system becomes unstable.
- For the case of stationary convection, if  $x > 2$ , both finite Larmor radius and rotation have a stabilizing effect on the system. On the other hand if  $x < 2$ , finite Larmor radius has stabilizing (or destabilizing) effect and rotation has destabilizing (or stabilizing) effect if

$$(x - 2) > (or <)$$

$$\left(\frac{T_{A_1}}{U}\right)^{1/2}$$

In the presence of finite Larmor radius effect and rotation if

$$\left[\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right]^2 > (or <) \left\{\sqrt{U}(x-2) + \sqrt{T_{A_1}}\right\}^2 (1+x)$$

the medium permeability has a destabilizing (or stabilizing) and the magnetic field has a stabilizing (or destabilizing) effect on the system.

- In the absence of rotation, finite Larmor radius always has a stabilizing effect on the system whereas the medium permeability and the magnetic field may have stabilizing effect for some wave numbers and destabilizing effect for other wave numbers given by

$$U(x-2)^2(1+x) \geq \left(\frac{1+x}{P} + \frac{Q_1}{\varepsilon}\right)^2$$

- The case of overstability is also considered. The conditions

$$\kappa < \left[\varepsilon + (1-\varepsilon)\frac{\rho_S C_S}{\rho_0 C}\right]\eta \text{ and } \kappa < \frac{\varepsilon^2 \left[\varepsilon + (1-\varepsilon)\frac{\rho_S C_S}{\rho_0 C}\right] \nu}{P^2 \left[\varepsilon P \left\{\sqrt{U}(x-2) + \sqrt{T_{A_1}}\right\}^2 - 2Q_1\right]}$$

are the sufficient conditions for the non-existence of overstability, the violation of which does not necessarily imply the occurrence of overstability.
